# Landscape Scale Conservation

- **Landscape scale stream fish conservation**
  - Develop strategy for efficiently and effectively conserving a suite of species over a large geographical extent
  - Consider biodiversity and resources available
  - Take existing conserved lands into consideration

# Objective

- **Identify the most valuable stream segments for fish conservation**

- Framework: “Freshwater Conservation Network Prioritization” (FCNP)
  1. Within conservation networks
  2. Complementary to conservation networks

**Vs. Blank Slate**

# Framework

Conservation Value →

## Freshwater Conservation Network Prioritization Framework

Species Representation:  
Distribution Models

Species Weighting:  
Vulnerability Scores

Scientific Name	Vulnerability Weight
AMBLOPLITES ARIOMMUS	1.53
AMBLOPLITES CONSTELLATUS	1.64
APLODINOTUS GRUNNIENS	1.28
AMEIURUS MELAS	1.31
AMEIURUS NATALIS	1.18
AMEIURUS NEBULOSUS	1.56
AMBLOPLITES RUPESTRIS	1.25
APHREODERUS SAYANUS	1.22
COTTUS BAIRDII	1.57
CYPRINELLA CAMURA	1.28
COTTUS CAROLINAE	1.46

Upstream Integrity:  
Penalty Curves

Mask:  
Conservation Network

Prioritization:  
Zonation 3.1

Complementary  
Priorities

Within Network  
Priorities

# Case Study: Missouri Wadeable Streams

- **Conservation network**
  - Publicly and privately owned areas which are managed with a primary purpose of conservation

# Conservation Value

- **Fish species**
  - Community samples
  - 1990-2011
  - N=~1,900
- **Rank value of stream segments based on**
  - Species Representation
  - Species Weights
  - Upstream Integrity/Connectivity

# Species Representation

- **Component Models**
  - Boosted Regression Trees
  - Random Forest Models
  - Generalized Additive Models
  - Multivariate Adaptive Regression Splines

# Species Representation

- **Component Models**

- Boosted Regression Trees
- Random Forest Models
- Generalized Additive Models
- Multivariate Adaptive Regression Splines

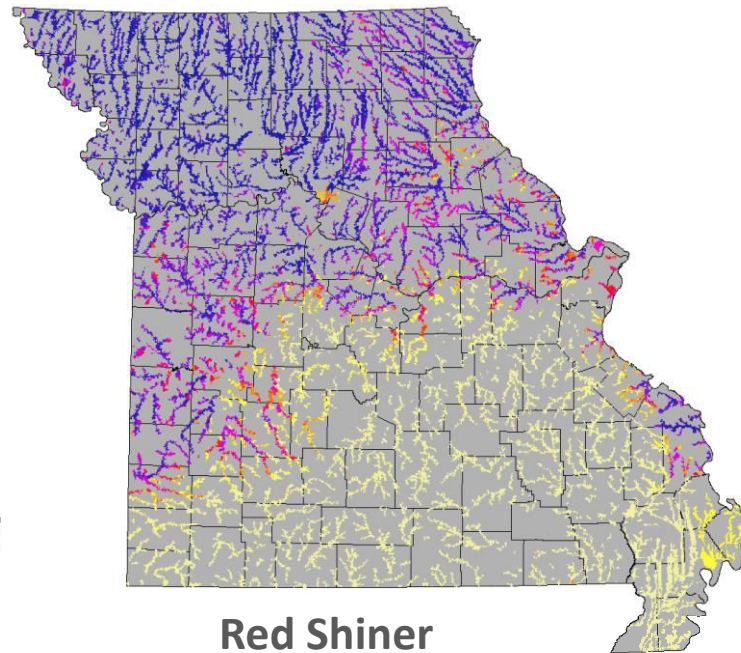

- **Ensemble models**

- Averaged results of component models which met minimum evaluation standards
  - Discrimination
    - AUC >0.6
  - Model Fit
    - Mean Absolute Error <0.125
  - Occurrence Frequency
    - Within 25%

# Distribution Models

- 79 Species: Models
- 54 Species: Point data with occurrence rates

Probability of Occurrence

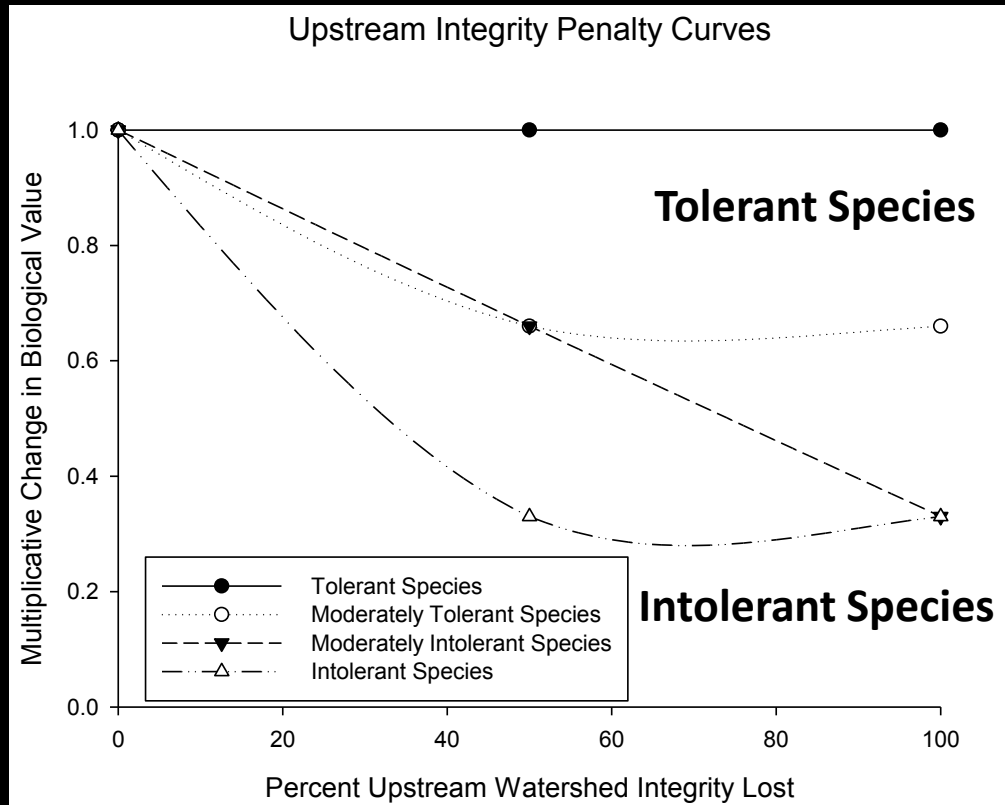

# Species Weight

- **Weighted based on species vulnerability**
  - **Vulnerability**
    - **Habitat, Temperature, and Flow**
    - **Dispersal, Rarity, Range**
    - **Habitat Connectivity**

# Upstream Integrity/Connectivity

- **Prioritize stream segments which maintain upstream connectivity**
- **Species specific penalty curves**
  - **Quantified species responses to upstream habitat degradation**

See Moilanen and Wintle. 2007. Conservation Biology. 21 (2): 355-364 for more information

# Zonation

# Zonation

# Zonation

# Zonation

# Zonation

# Zonation

# Zonation

# Conservation Value: FCNP

# Alternative Approaches

- **Blank Slate**

- Starting from scratch

- **Habitat Threat Index**

- Previously developed for MO
- Based on # of threats

# Comparisons

## • FCNP vs Blank Slate

- 2.1X more stream segments to represent all species
- Essentially equal representation across priority ranks
- Rare species rep
  - 3% fewer to 10% more sites
- Top 10% across MO
  - 71% of species lower levels of representation

## • Not as feasible

## • FCNP vs. Threat Index

- 2.6X fewer stream segments to represent all species
- Better species representation across all priority ranks
- Avg 5 more occurrences for rare species across priority ranks
- Top 10% across MO
  - 71% of species higher levels of representation

# Complementary Areas: Outside Existing Conservation Network

- **Opportunities for acquisition and partnerships**
- **High value locations**
  - Underrepresented species
  - Highly weighted species
  - Areas with sufficient upstream connectivity

# Within Network Rankings

- **Opportunities for protection, management, and restoration**
- **High value locations**
  - Rare species and high species richness
  - Highly weighted species
  - Areas with sufficient upstream connectivity

# Framework

- **Apply to systems of interest**

- Local
- State
- Regional
- National

- **Incorporate factors based on user needs**

- Conservation Networks
- Species of interest
- Emphasize representation or richness
- Species weighting options
- Include habitat integrity, connectivity or other factors such as cost, threats, etc.

# Take Home

- Incorporating established networks increases the feasibility of implementation
- Priorities based solely on habitat integrity resulted in lower species representation
- Constraining prioritization to established networks had minimal impact on efficiency
- Framework can be used to target restoration, land acquisition and partnerships
